Royal Society meeting:  
Beyond the symbols vs signals debate

# Meta-learning as bridging the neuro-symbolic gap in AI

Jane Wang  
Google DeepMind  
28-29 October 2024

# Two types of abstraction / generalization

## The two poles of abstraction: type 1 vs type 2

### Prototype-centric (value-centric) abstraction

- Set of prototypes + distance function
  - Example: classify face vs. non-face using abstract features
- Abstract wrt details not present in the prototypes
- Obtained by clustering concrete samples into prototypes
  - This is a value analogy!

### Program-centric abstraction

- Graph of (usually discrete) operators where input nodes can take different values within a type
  - Example: function that sorts a list
- Abstract wrt input nodes values
- Obtained by merging specialized functions under a new abstract signature
  - This is a program analogy!

```
a = [4, 5, 2, 6]
result = 0
for i, e in enumerate(a):
    result += i * e

b = [6, 3, 4, 7]
result = 0
for i, e in enumerate(b):
    result += i * e
```

→

```
def process_item(x):
    result = 0
    for i, e in enumerate(x):
        result += i * e
    return result
```

Francois Chollet,  
keynote talk at AGI-24

**“Meta-learning” is one method of learning useful representations**

**A process of learning priors or useful  
representations from previous experience to  
enable faster learning or better decisions**

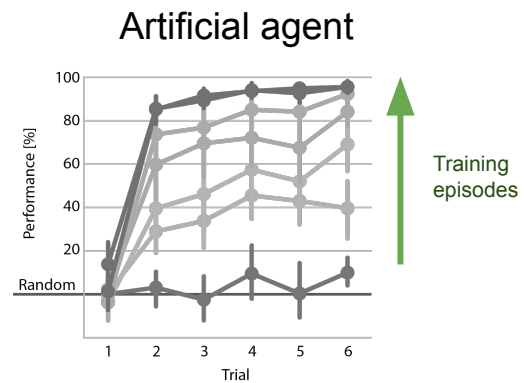

# The "Harlow task"

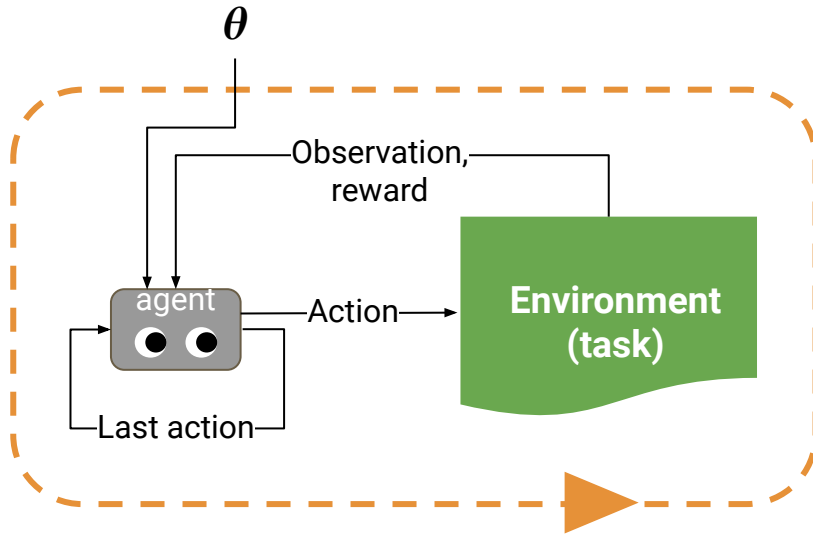

Harlow, 1949, *Psychological Review*

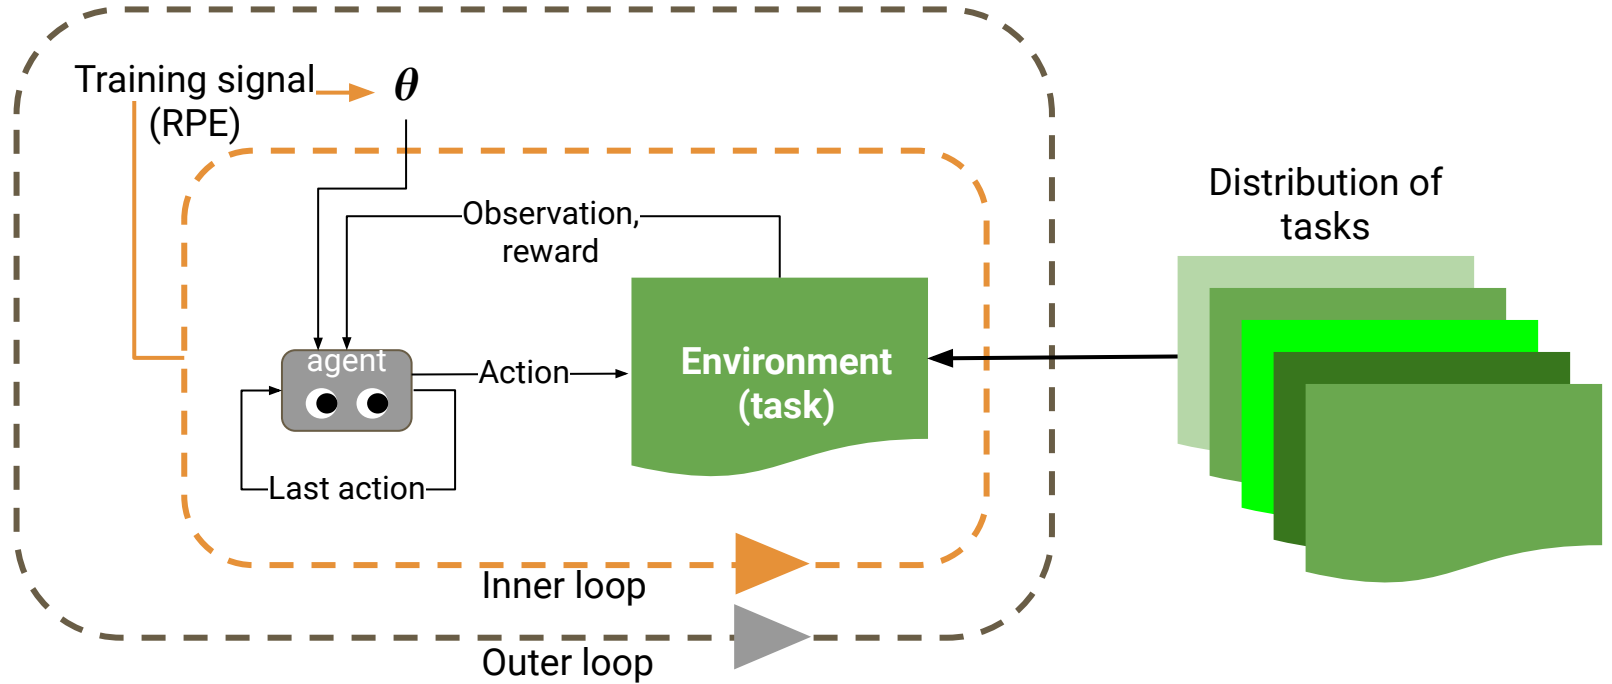

# Artificial agent (weights frozen)

# Meta-reinforcement learning

# Meta-reinforcement learning

# What is structured training data?

# In meta-learning, we only consider a subset of tasks of interest

Let's assume that all training tasks are sampled from a generative process with latent parameters  $w$  that generates a sequence of observations, conditioned on past states and actions

↑  
e.g. rules of physics, initial conditions, causal relationships, variables of interest, etc  
(note that  $N(w) \ll N(\text{tasks})$ )

# Tasks determine the states we can reach, with different utilities

Let's assume that all training tasks are sampled from a generative process with latent parameters  $w$  that generates a sequence of observations, conditioned on past states and actions

↑  
e.g. rules of physics, initial conditions, causal relationships, variables of interest, etc  
(note that  $N(w) \ll N(\text{tasks})$ )

Every episode  $i$ , sample a task  $T_i \sim \mathcal{T}(w)$

This task determines how an agent can interact with the environment to get to states with different utility or reward

Generative process with latent parameters  $w$  that generates task

$$T_i \sim \mathcal{T}(w)$$

We train a policy (agent) with learned parameters  $\theta$  that interacts with sampled task  $T_i$  to maximize expected total utility  $U$  (or minimize loss) for all the states  $s$  visited in task  $T$

$$U(T_i; \pi_\theta) = \sum_t u(s_{t,i}; \pi_\theta)$$

$$\max_{\theta} U(T_i; \pi_\theta)$$

Every episode  $i$  (gradient update), sample a task. Repeat for many  $T_i \sim \mathcal{T}(w)$

**If trained to optimal  $\theta^*$ , meta-learning parameters will represent sufficient statistics for this generative process**

**2-armed bandits**  
**independently drawn** from  
uniform Bernoulli distribution

Held constant for 100 trials  
=1 episode

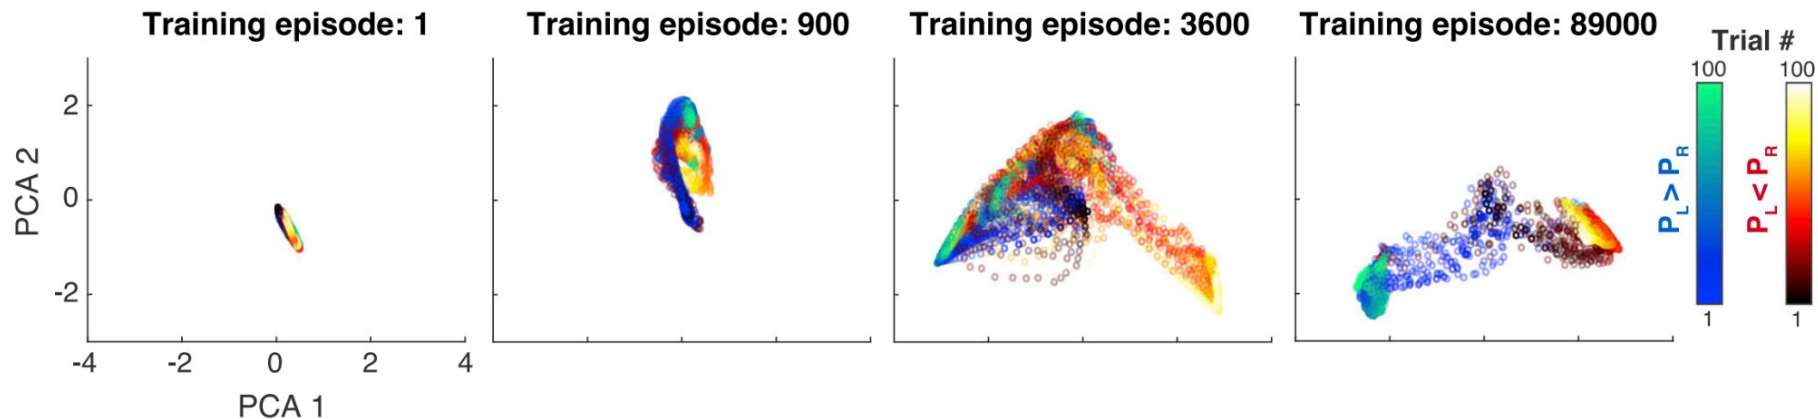

$p_i$  = probability of payout,  
drawn uniformly from  $[0, 1]$ ,

**2-armed bandits**  
independently drawn from  
uniform Bernoulli distribution

Held constant for 100 trials  
=1 episode

$p_i$  = probability of payout,  
drawn uniformly from  $[0, 1]$ ,

A good (useful) representation provides a mapping between raw sensory data and the underlying task-relevant variables of the set of tasks

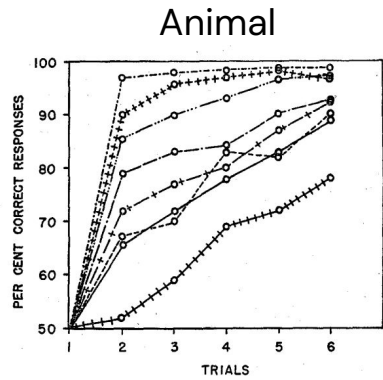

The end result of meta-learning is the acquisition of this representation

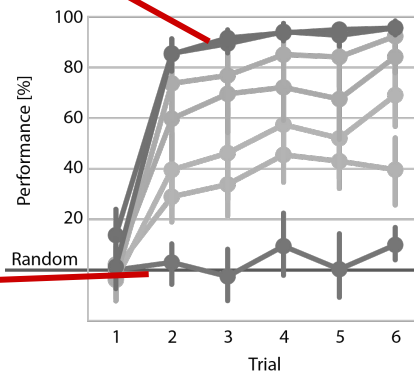

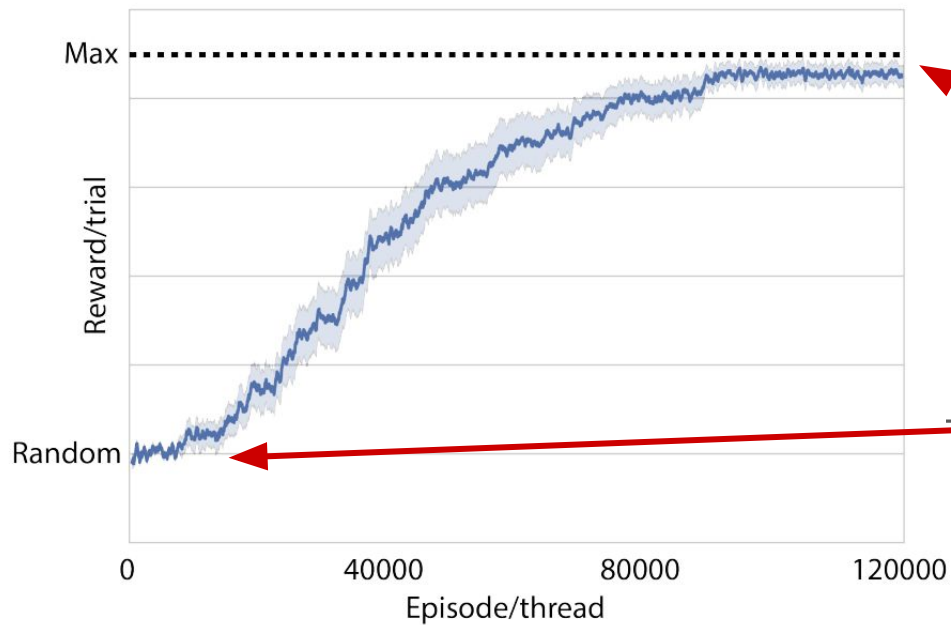

A good (useful) representation provides a mapping between raw sensory data and the underlying task-relevant variables of the set of tasks

The end result of meta-learning is the acquisition of this representation

**BUT** there is no guarantee that this representation can be learned in any reasonable amount of time!

# Alchemy: A meta-reinforcement learning benchmark

Chance performance

# Alchemy: A meta-reinforcement learning benchmark

**Improvement when training with auxiliary task specifically designed to give the right task-related representations**

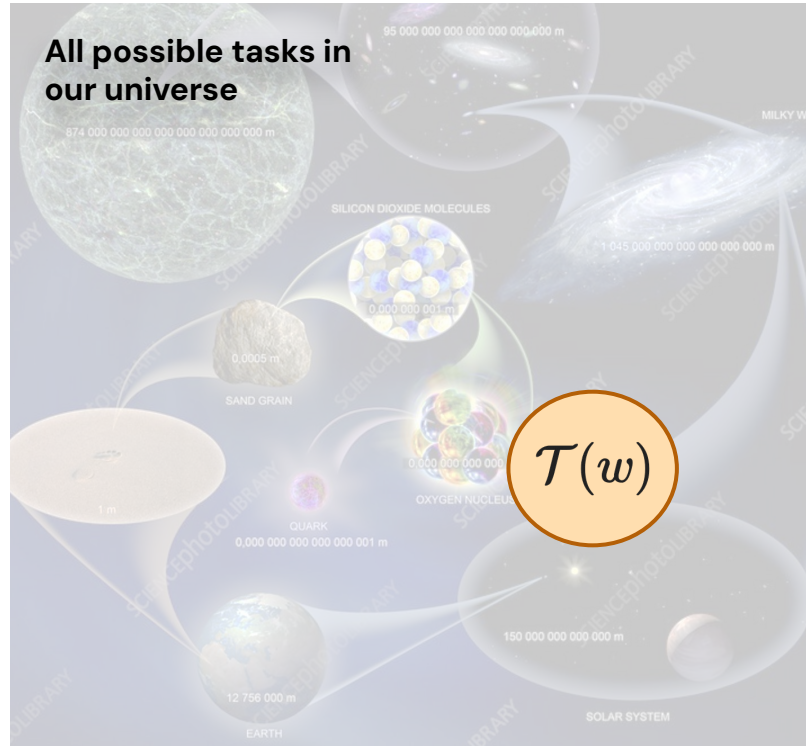

# ON THE ROLE OF PLANNING IN MODEL-BASED DEEP REINFORCEMENT LEARNING

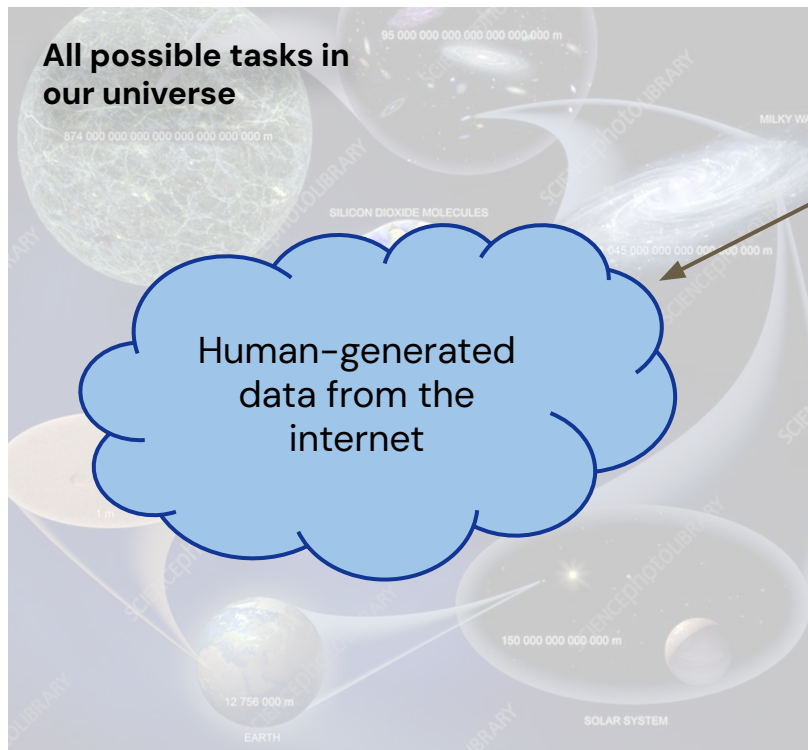

**Jessica B. Hamrick\***, **Abram L. Friesen**, **Feryal Behbahani**, **Arthur Guez**, **Fabio Viola**,  
**Sims Witherspoon**, **Thomas Anthony**, **Lars Buesing**, **Petar Veličković**, **Théophile Weber\***  
DeepMind, London, UK

- Looked at the role that planning plays in **generalization** for agents like MuZero
- Found it was more important to have the **right abstractions and representations** in the value and policy than learning a correct model of the environment or doing extensive planning
- How do we get our models to learn these right representations?

# Answer(?): first pre-train on real-world data at scale

# Answer(?): first pre-train on real-world data at scale

First train on this

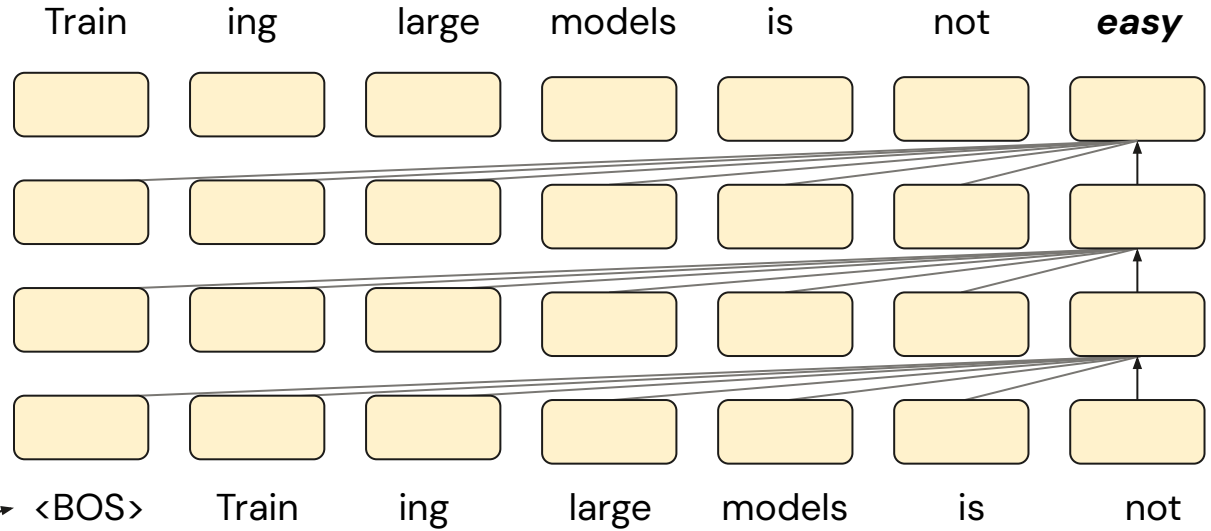

And then fine tune, few-shot, or even zero-shot prompt on this

$$\mathcal{T}(w)$$

Language model training is not active; they passively predict the next token in someone else's language

A lot of text on the internet, written by some humans

# In practice, it does surprisingly well (not human-level)

- LMs provide useful priors for causal reasoning mechanisms, e.g. for identifying causal structures from data
- LMs can be prompted to interactively use tools (e.g. APIs) to achieve a task

**Can we apply the same cognitive neuroscience tools to LLMs to better understand how they work?**

# The importance of the training dataset for in-context learning

- Investigated the emergence of in-context (meta) learning in transformer architectures
- Tested different characteristics of data distributions, including features that are prominent in natural language
- Burstiness, many classes, many-to-one label mappings all contributed to a tradeoff between in-context vs in-weights learning

# LLMs can learn causal reasoning even from passive data

## Passive learning of active causal strategies in agents and language models

Generalizable causal strategies and knowledge can be learned from passive data

Passive does not imply observational, can still learn from observing others perform experiments

# Meta-in-context learning in large language models

Large language models can not only perform in-context learning by learning from examples sampled from a single task, but can also exhibit meta-in-context learning by learning from examples taken from a series of tasks which are themselves sampled from a distribution, entirely within the prompt.

## Translate them for LLMs

### {Probabilistic reasoning instructions}

...  
 Q: The wheel of fortune contains 6 sections labeled F and 4 sections labeled J. The urn F contains (8, 2) and the urn J contains (2, 8) red/blue balls. A red ball was drawn. What is the probability that it was drawn from Urn F? (Give your probability estimate on the scale from 0 to 1 rounded to two decimal places)

A: I estimate the probability of the red ball to be drawn from the urn F to be 0.

### {BART instructions}

...  
 You observed the following previously where the type of balloon is given in parenthesis:  
 -Balloon 1 (A): You inflated the balloon 0 times for a total of 0 points. It did not explode.  
 -Balloon 2 (C): You inflated the balloon 4 times for a total of 4 points. It did not explode.  
 Q: You are currently with Balloon 3 which is a balloon of type A. What do you do? (Option 1 for 'skip' or 2 for 'inflate')  
 A: Option

# The next generation of foundation models: foundation agents

From **static data** to **experiential data**

- Embodied
- Agentic
- Causal
- Persistent over some duration of time
- Contains feedback signals which can be used to learn

## Conclusions

- Meta-learning, or learning to learn, hinges on acquiring useful representations that enable generalization.
- Large language models demonstrate implicit meta-learning through their ability to generalize from massive text data.
- Cognitive science provides a framework for analyzing the representations and cognitive abilities of these models.
- Embodied AI, with its emphasis on interaction and experience, offers a path towards more general and adaptable intelligence.
